

## Sampling Variability and Reliability of ACS Data

American Community Survey (ACS) estimates are period estimates that describe the average characteristics of population and housing over a period of data collection. The 2008-2012 5-year ACS estimates are averages over the period from January 1, 2008 through December 31, 2012. Multiyear estimates cannot be used to say what is going on in any particular year in the period, only what the average value is over the full period.

The ACS, like any statistical activity, is subject to error. ACS data includes a **margin of error** for every estimate. Ninety-percent confidence intervals define a range expected to contain the true value of an estimate with a level of confidence of 90 percent. Margins of error (MOE) are easily converted into these confidence ranges. For example, from the 2008-2012 ACS, per capita income for the State of Iowa is \$26,545. By adding and subtracting the margin of error from the estimate, we can calculate the 90 percent confidence interval for that estimate:

$$\$26,545 - \$136 = \$26,409$$

$$\$26,545 + \$136 = \$26,681$$

Therefore, we can be 90 percent confident that the true per capita income for Iowa falls somewhere between \$26,409 and \$26,681.

Environmental Systems Research Institute, Inc. (Esri) has developed a method to help users determine the quality of an estimate. Esri has simplified the interpretation of the MOE by adding color-coded symbols, based on Coefficient of Variation (CV) to indicate the reliability of the data. A coefficient of variation provides a measure of the relative amount of sampling error that is associated with a sample estimate. The CV is calculated as the ratio of the Standard Error (SE) for an estimate to the estimate itself and is usually expressed as a percent. It is a useful barometer of the stability, and thus the usability of a sample estimate.

[Using Esri breakpoints and definitions](#), the Legislative Services Agency uses the following symbols to determine the reliability of ACS data:

-  **High Reliability:** Small CVs, less than or equal to 12 percent, are flagged with a green check to indicate that the sampling error is small relative to the estimate and the estimate is reasonably reliable.
-  **Medium Reliability:** Estimates with CVs between 12 and 40 percent are flagged with a yellow exclamation mark—use with caution.
-  **Low Reliability:** Large CVs, over 40 percent, are flagged with a red “x” to indicate that the sampling error is large relative to the estimate. The estimate is considered very unreliable.

For information relating to Esri Reliability Symbols [click here](#).

For more information on ACS sample design, estimation methodology, and accuracy of the multiyear ACS estimates [click here](#). For more information on how to access and use the ACS data [click here](#).

**The following tables display the estimates, margin of error, and reliability of all ACS estimates used in the interactive maps.**
